The broad spectrum anti-proliferative agent is actinomycin D inhibits cell growth by preventing the progression from G1 into S phase of the cell cycle. This drug induces cell cycle arrest by blocking the transcription of several important genes that are required for progression into S phase. This inhibition leads to the accumulation of cells in the G1 phase. To understand the mechanism of action of actinomycin D and other anti-proliferative agents, the induction of a temporary arrest of protein synthesis and its effect on key regulatory proteins were studied. The actinomycin D-induced block of protein synthesis was reversible. The S phase-dependent cyclin-dependent kinase 2 (CDK2) and DNA polymerase delta (pol delta) were temporarily inhibited by actinomycin D, and the inhibition of these proteins correlated with the selective induction of growth arrest. The cyclin E, T, and B were inhibited simultaneously by actinomycin D, indicating that the inhibition of the cell cycle progression occurred at the G1/S transition. The CDK2 kinase activity was reversibly inhibited by actinomycin D. The phosphorylation of retinoblastoma (RB) protein, a CDK2 substrate, was also inhibited by actinomycin D and this inhibition was correlated with the dephosphorylation of RB. The dephosphorylation of RB was effected by dephosphorylation of CDK2. The inhibitor 2,4,5-triidodecyl-1,1-bisphosphonate, an inhibitor of CDKs and pol delta, also induced reversible cell cycle arrest. A cyclin E antibody, an inhibitor of G1/S transition, induced reversible cell cycle arrest. It is concluded that actinomycin D induces reversible cell cycle arrest by inhibiting the expression of cyclin E and RB.The Penguin Press. 1920. First Edition. Hardcover. Good (tight and square
